## 1 Introduction

### 1.1 Covering codes. The length function. Saturating sets in projective spaces

Let $F_{q}$ be the Galois field with $q$ elements. Let $F_{q}^{n}$ be the $n$-dimensional vector space over $F_{q}$. Denote by $[n, n-r]_{q}$ a $q$-ary linear code of length $n$ and codimension (redundancy) $r$, that is, a subspace of $F_{q}^{n}$ of dimension $n-r$. The sphere of radius $R$ with center $c$ in $F_{q}^{n}$ is the set $\left\{v: v \in F_{q}^{n}, d(v, c) \leq R\right\}$ where $d(v, c)$ is the Hamming distance between vectors $v$ and $c$.

Definition 1.1. (i) The covering radius of a linear $[n, n-r]_{q}$ code is the least integer $R$ such that the space $F_{q}^{n}$ is covered by spheres of radius $R$ centered at codewords.
(ii) A linear $[n, n-r]_{q}$ code has covering radius $R$ if every column of $F_{q}^{r}$ is equal to a linear combination of at most $R$ columns of a parity check matrix of the code, and $R$ is the smallest value with such a property.

Definitions 1.1 (i) and 1.1 (ii) are equivalent. Let an $[n, n-r]_{q} R$ code be an $[n, n-r]_{q}$ code with covering radius $R$. For an introduction to coverings of vector Hamming spaces over finite fields, see [6,7].

The covering density $\mu$ of an $[n, n-r]_{q} R$-code is defined as

$$
\begin{equation*}
\mu=\frac{1}{q^{r}} \sum_{i=0}^{R}(q-1)^{i}\binom{n}{i} \geq 1 . \tag{1.1}
\end{equation*}
$$

The covering quality of a code is better if its covering density is smaller. For fixed $q, r, R$, the covering density of an $[n, n-r]_{q} R$ code decreases with decreasing $n$.

Codes investigated from the point view of the covering quality are usually called covering codes [7]; see an online bibliography [21], works [6, 8, 10, 12 15, 19, 20], and the references therein.

Definition 1.2. [6,7] The length function $\ell_{q}(r, R)$ is the smallest length of a $q$-ary linear code with covering radius $R$ and codimension $r$.

From (1.1), see also Definition 1.1(ii), one can get an approximate lower bound on $\ell_{q}(r, R)$. The main term of the sum in (1.1) is $(q-1)^{R}\binom{n}{R}$; it implies

$$
\mu \approx \frac{1}{q^{r}}(q-1)^{R}\binom{n}{R} \approx q^{R-r} \frac{n^{R}}{R!} \gtrsim 1, n \gtrsim \sqrt[R]{R!} \cdot q^{(r-R) / R},
$$

and, in a more general form,

$$
\begin{equation*}
\ell_{q}(r, R) \gtrsim c q^{(r-R) / R} \tag{1.2}
\end{equation*}
$$

where $c$ is independent of $q$ but it is possible that $c$ is dependent of $r$ and $R$. In 10], see also the references therein including [8, 12], the bound (1.2) is given in another (asymptotic) form and infinite families of covering codes, achieving the bound, are obtained for the following situations: $r=t R$, arbitrary $q ; r \neq t R, q=\left(q^{\prime}\right)^{R} ; R=s R^{\prime}, r=R t+s, q=\left(q^{\prime}\right)^{R^{\prime}}$. Here $t, s$ are integers, $q^{\prime}$ is a prime power. In the general case, for arbitrary $r, R, q$ the problem to achieve the bound (1.2) is open.

In the last decades, upper bounds on $\ell_{q}(r, R)$ have been intensively investigated, see [6-10, 12 $-15,19,21]$ and the references therein.

The goal of this work is to obtain new upper bounds on the length functions $\ell_{q}(4,3)$ and $\ell_{q}(5,3)$ with $r \neq t R$ and arbitrary $q$, in particular with $q \neq\left(q^{\prime}\right)^{3}$ where $q^{\prime}$ is a prime power. It is an open problems.

Let $\operatorname{PG}(N, q)$ be the $N$-dimensional projective space over the field $F_{q}$; see $16-18$ for an introduction to the projective spaces over finite fields, see also [14, 17, 19, 20 for connections between coding theory and Galois geometries.

Effective methods to obtain upper bounds on $\ell_{q}(r, R)$ are connected with saturating sets in $\operatorname{PG}(N, q)$.

Definition 1.3. A point set $\mathcal{S} \subseteq \mathrm{PG}(N, q)$ is $\rho$-saturating if for any point $A$ of $\mathrm{PG}(N, q) \backslash$ $\mathcal{S}$ there exist $\rho+1$ points in $\mathcal{S}$ generating a subspace of $\operatorname{PG}(N, q)$ containing $A$, and $\rho$ is the smallest value with such property.

By Definition 1.3 , every point $A$ from $\operatorname{PG}(N, q)$ can be written as a linear combination of at most $\rho+1$ points of a $\rho$-saturating set, cf. Definition 1.1(ii).

Saturating sets are considered, for instance, in $[1,3,6,8,12,14,15,19,20,24]$. In the literature, saturating sets are also called "saturated sets", "spanning sets", "dense sets".

Let $s_{q}(N, \rho)$ be the smallest size of a $\rho$-saturating set in $\operatorname{PG}(N, q)$.
If $q$-ary positions of a column of an $r \times n$ parity check matrix of an $[n, n-r]_{q} R$ code are treated as homogeneous coordinates of a point in $\operatorname{PG}(r-1, q)$ then this parity check matrix defines an $(R-1)$-saturating set of size $n$ in $\operatorname{PG}(r-1, q)$ [8-10, 14, 15, 19, 20]. So,
there is a one-to-one correspondence between $[n, n-r]_{q} R$ codes and ( $R-1$ )-saturating sets in $\mathrm{PG}(r-1, q)$. Therefore,

$$
\ell_{q}(r, R)=s_{q}(r-1, R-1)
$$

in particular, $\ell_{q}(4,3)=s_{q}(3,2), \ell_{q}(5,3)=s_{q}(4,2)$.
Complete arcs in $\operatorname{PG}(N, q)$ are an important class of saturating sets. An $n$-arc in $\mathrm{PG}(N, q)$ with $n>N+1$ is a set of $n$ points such that no $N+1$ points belong to the same hyperplane of $\operatorname{PG}(N, q)$. An $n$-arc of $\operatorname{PG}(N, q)$ is complete if it is not contained in an $(n+1)$-arc of $\operatorname{PG}(N, q)$. A complete arc in $\operatorname{PG}(N, q)$ is an $(N-1)$-saturating set. Points (in the homogeneous coordinates) of a complete $n$-arc in $\mathrm{PG}(N, q)$, treated as columns, form a parity check matrix of an $[n, n-(N+1), N+2]_{q} N$ maximum distance separable (MDS) code. If $N=2,3$ these codes are quasiperfect.

Let $s_{q}^{\text {arc }}(N, N-1)$ be the smallest size of a complete arc in $\mathrm{PG}(N, q)$. By above,

$$
\ell_{q}(N+1, N)=s_{q}(N, N-1) \leq s_{q}^{\operatorname{arc}}(N, N-1)
$$

### 1.2 Covering codes with radius 3

For arbitrary $q$, covering $[n, n-r]_{q} 3$ codes of length close to lower bound (1.2) are known only for $r=t R=3 t$ (10, 12]. In particular, the following bounds are obtained by algebraic constructions [10, Sect. 5, eq. (5.2)], [12, Th. 12]:

$$
\begin{aligned}
& \ell_{q}(r, 3) \leq 3 q^{(r-3) / 3}+q^{(r-6) / 3}, r=3 t \geq 6, r \neq 9, q \geq 5, \text { and } r=9, q=16, q \geq 23 . \\
& \ell_{q}(r, 3) \leq 3 q^{(r-3) / 3}+2 q^{(r-6) / 3}+1, r=9, q=7,8,11,13,17,19 \\
& \ell_{q}(r, 3) \leq 3 q^{(r-3) / 3}+2 q^{(r-6) / 3}+2, r=9, q=5,9
\end{aligned}
$$

If $r=3 t+1$ or $r=3 t+2$, covering codes of length close to lower bound (1.2) are known only when $q=\left(q^{\prime}\right)^{3}$, where $q^{\prime}$ is a prime power [8, 10, 15]. In particular, the following bounds are obtained by algebraic constructions, see [8, 9], [10, Sect. 5, eqs. (5.3),(5.4)]:

$$
\begin{aligned}
& \ell_{q}(r, 3) \leq\left(4+\frac{4}{\sqrt[3]{q}}\right) q^{(r-3) / 3}, r=3 t+1 \geq 4, q=\left(q^{\prime}\right)^{3} \geq 64 \\
& \ell_{q}(r, 3) \leq\left(9-\frac{8}{\sqrt[3]{q}}+\frac{4}{\sqrt[3]{q^{2}}}\right) q^{(r-3) / 3}, r=3 t+2 \geq 5, q=\left(q^{\prime}\right)^{3} \geq 27
\end{aligned}
$$

For arbitrary $q \neq\left(q^{\prime}\right)^{3}$, in the literature, computer results are given for $[n, n-4]_{q} 3$ codes with $q \leq 563\left[13\right.$, Tab. 1] and $[n, n-5]_{q} 3$ codes with $q \leq 43$ [9, Tab. 1], [13, Tab. 2].

In this work, by computer search, we obtain new results for $[n, n-4,5]_{q} 3$ quasiperfect MDS codes with $q \leq 3323, q=3511,3761,4001$, and $[n, n-5,5] q 3$ quasiperfect Almost

MDS codes with $q \leq 563$. This gives upper bounds on $\ell_{q}(4,3)$ and $\ell_{q}(5,3)$ for a set of values $q$ larger than the one in [9, 13].

The following theorem collects the new results of this paper, see Sections 3 and 4 .
Theorem 1.4. Let $c_{4}=2.8$ and $c_{5}=3$. For the length function $\ell_{q}(r, 3)$ and for the smallest size $s_{q}(r-1,2)$ of a 2-saturating set in the projective space $\operatorname{PG}(r-1, q)$ the following upper bounds hold.

$$
\begin{gather*}
\text { (i) } \quad \ell_{q}(4,3)=s_{q}(3,2) \leq s_{q}^{\operatorname{arc}}(3,2)<c_{4} \sqrt[3]{\ln q} \cdot q^{(4-3) / 3}=c_{4} \sqrt[3]{\ln q} \cdot \sqrt[3]{q}  \tag{i}\\
\text { for } 11 \leq q \leq 3323 \text { and } q=8,3511,3761,4001 ; \\
\\
\quad \ell_{q}(4,3)=s_{q}(3,2)<c_{4} \sqrt[3]{\ln q} \cdot q^{(4-3) / 3}=c_{4} \sqrt[3]{\ln q} \cdot \sqrt[3]{q} \text { for } q=9 \\
\text { (ii) } \quad \ell_{q}(5,3)=s_{q}(4,2)<c_{5} \sqrt[3]{\ln q} \cdot q^{(5-3) / 3}=c_{5} \sqrt[3]{\ln q} \cdot \sqrt[3]{q^{2}} \quad \text { for } 5 \leq q \leq 563
\end{gather*}
$$

Note that an $[n, n-4,5]_{q} 3$ quasiperfect MDS code corresponds to a complete $n$-arc in $\operatorname{PG}(3, q)$. So, we obtained also upper bounds on $s_{q}^{\text {arc }}(3,2)$ and $s_{q}(3,2)$.

We emphasize that, for $r \neq 3 t$ and $q \neq\left(q^{\prime}\right)^{3}$, the new bounds of Theorem 1.4 have the form

$$
\ell_{q}(r, 3)<c \sqrt[3]{\ln q} \cdot q^{(r-3) / 3}, \quad c \text { is a universal constant, } \quad r=4,5
$$

As far as it is known to the authors, such bounds have not been previously described in the literature.

Our results, in particular figures and observations in Sections 3 and 4, allow us to conjecture the following.

Conjecture 1.5. The bounds of Theorem 1.4 hold for all $q$.
The paper is organized as follows. In Section 2, we describe a leximatrix algorithm to obtain parity check matrices of covering codes. In Sections 3 and 4 , upper bounds on the length functions $\ell_{q}(4,3)$ and $\ell_{q}(5,3)$ are considered. In Conclusion, the results of this work are briefly analyzed; some tasks for investigation of the leximatrix algorithm are formulated. In Appendix, tables with sizes of codes obtained in this work are given.

## 2 Leximatrix algorithm to obtain parity check matrices of covering codes

The following is a version of the recursive g-parity check algorithm for greedy codes, see e.g. [5, p. 25], [22, [23, Section 7].

Let $F_{q}=\{0,1, \ldots, q-1\}$ be the Galois field with $q$ elements.

If $q$ is prime, the elements of $F_{q}$ are treated as integers modulo $q$.
If $q=p^{m}$ with $p$ prime and $m \geq 2$, the elements of $F_{p^{m}}$ are represented by integers as follows: $F_{p^{m}}=F_{q}=\left\{0,1=\alpha^{0}, 2=\alpha^{1}, \ldots, u=\alpha^{u-1}, \ldots, q-1=\alpha^{q-2}\right\}$, where $\alpha$ is a root of a primitive polynomial of $F_{p^{m}}$.

For a $q$-ary code of codimension $r$, covering radius $R$, and minimum distance $d=R+2$, we construct a parity check matrix from nonzero columns $h_{i}$ of the form

$$
h_{i}=\left(x_{1}^{(i)}, x_{2}^{(i)}, \ldots, x_{r}^{(i)}\right)^{T}, x_{u}^{(i)} \in F_{q},
$$

where the first (leftmost) non-zero element is 1 . The number of distinct columns is $\left(q^{r}-1\right) /(q-1)$. For $h_{i}$ we put $i=\sum_{u=1}^{r} x_{u}^{(i)} q^{r-u}$. We order the columns in the list as $h_{1}, h_{2}, \ldots, h_{\left(q^{r}-1\right) /(q-1)}$. The columns of the list are candidates to be included in the parity check matrix.

By above, a column $h_{i}$ is treated as its number $i$ in our list written in the $q$-ary scale of notation. The considered order of columns is lexicographical.

The first column of the list should be included into the matrix. Then step-by-step, one takes the next column from the list which cannot be represented as a linear combination of at most $R$ columns already chosen. The process ends when no new column may be included into the matrix. The obtained matrix $H_{n}$ is a parity check matrix of an $[n, n-r, R+2]_{q} R$ code.

We call leximatrix and leximatrix code the obtained parity check matrix and the corresponding code.

It is important to note that for prime $q$, length $n$ of a leximatrix code and form of the leximatrix $H_{n}$ depend on $q$ and $R$ only. No other factors affect code length and structure.

For non-prime $q$, the length $n$ of a leximatrix code depends on $q$ and on the form of the primitive polynomial of the field. In this work, we use primitive polynomials that are created by the program system MAGMA [4] by default, see Table A. In any case, the choice of the polynomial changes the leximatrix code length unessentially.

By the leximatrix algorithm, if $R=1$, we obtain the $q$-ary Hamming code. If $R=2$, we obtain a quasiperfect $[n, n-r, 4]_{q} 2$ code; for $r=3$ such a code is MDS and corresponds to a complete arc in $\mathrm{PG}(2, q)$. If $R=3$, we obtain a quasiperfect $[n, n-r, 5]_{q} 3$ code; for $r=4$ such a code is MDS and corresponds to a complete arc in $\operatorname{PG}(3, q)$; for $r=5$ it is Almost MDS.

Let $n_{q}^{\mathrm{L}}(r, R)$ be length of the $q$-ary leximatrix code of codimension $r$ and covering radius $R$. It is assumed that for a non-prime field $F_{q}$, one uses the primitive polynomial created by the program system MAGMA [4] by default; in particular, for non-prime $q<4000$, the polynomial from Table A should be taken.

Future, we represent length of an $\left[n_{q}^{L}(r, R), n_{q}^{L}(r, R)-r, R+2\right]_{q} R$ leximatrix code in

Table A. Primitive polynomials used for leximatrix $[n, n-r, 5]_{q} 3$ quasiperfect codes with non-prime $q$

the form

$$
\begin{equation*}
n_{q}^{\mathrm{L}}(r, R)=c_{q}^{\mathrm{L}}(r, R) \sqrt[R]{\ln q} \cdot q^{(r-R) / r} \tag{2.1}
\end{equation*}
$$

where $c_{q}^{\mathrm{L}}(r, R)$ is a coefficient entirely given by $r, R, q$.
Remark 2.1. In the literature on the projective geometry, the columns are considered as points in homogenous coordinates; the algorithm, described above, is called an "algorithm with fixed order of points" (FOP) [2, 3].

## 3 Upper bounds on the length functions $\ell_{q}(4,3)$

The following properties of the leximatrix algorithm are useful for implementation.
Proposition 3.1. Let $q$ be a prime. Then the $v$-th column of the leximatrix of an $[n, n-4,5]_{q} 3$ code is the same for all $q \geq q_{0}(v)$ where $q_{0}(v)$ is large enough.
Proof. Let $H_{j}=\left[h^{(1)}, h^{(2)}, \ldots, h^{(j)}\right]$ be the matrix obtained in the $j$-th step of the leximatrix algorithm. Here $h^{(v)}$ is a column of the matrix. A column from the list, not included in $H_{j}$, is covered by $H_{j}$ if it can be represented as a linear combination of at
most 3 columns of $H_{j}$. Suppose that $h^{(j)}=h_{s}$, where $h_{s}$ is the $s$-th column in the lexicographical list of candidates. A column $Q=h_{u} \notin H_{j}$ is the next chosen column, if and only if all the columns $h_{m}$ with $m \in[s+1, u-1]$ are covered by $H_{j}$. This means that, for any $m \in[s+1, u-1]$, at least one of the determinants $\operatorname{det}\left(h^{\left(v_{1}\right)}, h^{\left(v_{2}\right)}, h^{\left(v_{3}\right)}, h_{m}\right)$, with $h^{\left(v_{1}\right)}, h^{\left(v_{2}\right)}, h^{\left(v_{3}\right)} \in H_{j}$, is equal to zero modulo $q$. This can happen only in two cases:

- $\operatorname{det}\left(h^{\left(v_{1}\right)}, h^{\left(v_{2}\right)}, h^{\left(v_{3}\right)}, h_{m}\right)=0$, we say that $h_{m}$ is "absolutely" covered by $H_{j}$;
- $\operatorname{det}\left(h^{\left(v_{1}\right)}, h^{\left(v_{2}\right)}, h^{\left(v_{3}\right)}, h_{m}\right)=B \neq 0$, but $B \equiv 0 \bmod q$.

For $q$ large enough, $q$ does not divide any of the possible values of $B$ and then, at least for $j$ relatively small, the columns covered are just the absolutely covered columns. Therefore, when $q$ is large enough the leximatrices share a certain number of columns.

The values of $q_{0}(v)$ can be found with the help of calculations based on the proof of Proposition 3.1. Also, we can directly consider leximatrices for a convenient region of $q$.

Example 3.2. Values of $q_{0}(v), v \leq 20$, together with columns $\left(x_{1}^{(v)}, x_{2}^{(v)}, x_{3}^{(v)}, x_{4}^{(v)}\right)^{T}$, are given in Table 1. So, for all prime $q \geq 233$ (resp. $q \geq 1321$ ) the first 14 (resp. 20) columns of a parity check matrix of an $[n, n-4,5]_{q} 3$ MDS leximatrix code are as in Table B.

Table B. The first 20 columns of parity check matrices of $[n, n-4,5]$ leximatrix MDS codes, $q$ prime

| $v$ | $x_{1}^{(v)}$ | $x_{2}^{(v)}$ | $x_{3}^{(v)}$ | $x_{4}^{(v)}$ | $q_{0}(v)$ | $v$ | $x_{1}^{(v)}$ | $x_{2}^{(v)}$ | $x_{3}^{(v)}$ | $x_{4}^{(v)}$ | $q_{0}(v)$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| 10 | 1 | 6 | 8 | 9 | 41 | 20 | 1 | 16 | 9 | 38 | 1321 |

Proposition 3.3. (i) There exist $[7,7-4,5]_{8} 3$ and $[7,7-4,4]_{9} 3$ codes, length $n$ of which satisfies $n<2.8 \sqrt[3]{q \ln q}$.
(ii) There exist $\left[n_{q}^{\mathrm{L}}(4,3), n_{q}^{\mathrm{L}}(4,3)-4,5\right]_{q} 3$ quasiperfect $M D S$ leximatrix codes of length $n_{q}^{\mathrm{L}}(4,3)<2.8 \sqrt[3]{q \ln q}$ for $11 \leq q \leq 3323$ and $q=3511,3761,4001$.

Proof. (i) The existence of the codes is noted in [13, Tab. 1], see also the references therein.
(ii) The needed codes are obtained by computer search, using the leximatrix algorithm, Proposition 3.1, and Example 3.2.

Proposition 3.3 implies assertions of Theorem 1.4 (i).
Lengths of $\left[n_{q}^{L}(4,3), n_{q}^{L}(4,3)-4,5\right]_{q} 3$ leximatrix quasiperfect MDS codes are collected in Table 1 (see Appendix) and presented in Figure 1 by the bottom solid black curve. The bound $2.8 \sqrt[3]{q \ln q}$ is shown in Figure 1 by the top dashed-dotted red curve.

Figure 1: Lengths $n_{q}^{L}(4,3)$ of $\left[n_{q}^{L}(4,3), n_{q}^{L}(4,3)-4,5\right]_{q} 3$ leximatrix codes (quasiperfect MDS codes) (bottom solid black curve) vs bound $2.8 \sqrt[3]{q \ln q}$ (top dashed-dotted red curve), all $q \leq 3323$ and $q=3511,3761,4001$. Vertical magenta line marks region $q \leq 3323$

We denote by $\delta_{q}(4,3)$ the difference between the bound $2.8 \sqrt[3]{q \ln q}$ and length $n_{q}^{\mathrm{L}}(4,3)$ of the leximatrix code. So,

$$
\delta_{q}(4,3)=2.8 \sqrt[3]{q \ln q}-n_{q}^{\mathrm{L}}(4,3)
$$

The difference $\delta_{q}(4,3)$ is presented in Figure 2 .

Figure 2: Difference $\delta_{q}(4,3)$ between bound $2.8 \sqrt[3]{q \ln q}$ and length $n_{q}^{\mathrm{L}}(4,3)$ of $\left[n_{q}^{\mathrm{L}}(4,3), n_{q}^{\mathrm{L}}(4,3)-4,5\right]_{q} 3$ leximatrix codes, $q \leq 3323$ and $q=3511,3761,4001$

By (2.1), we represent length of an $\left[n_{q}^{L}(4,3), n_{q}^{L}(4,3)-4,5\right]_{q} 3$ leximatrix code in the form

$$
\begin{equation*}
n_{q}^{\mathrm{L}}(4,3)=c_{q}^{\mathrm{L}}(4,3) \sqrt[3]{q \ln q} \tag{3.1}
\end{equation*}
$$

where $c_{q}^{\mathrm{L}}(4,3)$ is a coefficient entirely given by $q$. The coefficients $c_{q}^{\mathrm{L}}(4,3)=\frac{n_{q}^{\mathrm{L}}(4,3)}{\sqrt[3]{q \ln q}}$ are shown in Figure 3 .

Figure 3: Coefficients $c_{q}^{\mathrm{L}}(4,3)=n_{q}^{\mathrm{L}}(4,3) / \sqrt[3]{q \ln q}$ for $\left[n_{q}^{\mathrm{L}}(4,3), n_{q}^{\mathrm{L}}(4,3)-4,5\right]_{q} 3$ leximatrix codes (quasiperfect MDS codes), $q \leq 3323$ and $q=3511,3761,4001$

Observation 3.4. (i) The difference $\delta_{q}(4,3)$ tends to increase when $q$ grows, see Figures 1 and 2 .
(ii) Coefficients $c_{q}^{L}(4,3)$ oscillate around the horizontal line $y=2.64$, see Figure 3 .

Observation $3.4($ i $)$ gives rise to Conjecture 1.5 for $[n, n-4]_{q} 3$ codes.
Remark 3.5. It is interesting that the oscillation of the coefficients $c_{q}^{\mathrm{L}}(4,3)$ around a horizontal line, in principle, is similar to the oscillation of the values $h^{\mathrm{L}}(q)$ around a horizontal line in [2, Fig. 12, Observation 3.7], [3, Fig. 5, Observation 3.7].

In the papers $\left[2,3\right.$, small complete $t_{2}^{L}(2, q)$-arcs in the projective plane $\operatorname{PG}(2, q)$ are constructed by computer search using algorithm with fixed order of points (FOP). These arcs correspond to $\left[t_{2}^{L}(2, q), t_{2}^{L}(2, q)-3,4\right]_{q} 2$ quasiperfect MDS codes while the algorithm FOP is analogous to the leximatrix algorithm of Section 2 . Moreover, the value $h^{\mathrm{L}}(q)$ is defined in [2, 3] as $h^{\mathrm{L}}(q)=t_{2}^{L}(2, q) / \sqrt{3 q \ln q}$. So, see (3.1), the coefficients $c_{q}^{\mathrm{L}}(4,3)$ and the values $\hbar^{\llcorner }(q)$ have the similar nature. It is possible that the oscillations mentioned have similar reasons too. However, in the present time the enigma of the oscillations is incomprehensible,

## 4 Upper bounds on the length functions $\ell_{q}(5,3)$

Proposition 4.1. (i) There exist $[n, n-5,4]_{q} 3$ codes with $n<3 \sqrt[3]{q^{2} \ln q}$ for $5 \leq q<37$.
(ii) There exist $\left[n_{q}^{L}(5,3), n_{q}^{L}(5,3)-5,5\right]_{q} 3$ Almost MDS leximatrix codes with $n_{q}^{L}(5,3)<$ $3 \sqrt[3]{q^{2} \ln q}$ for $37 \leq q \leq 563$.

Proof. (i) The existence of the codes is noted in [9, Tab. 1], [13, Tab. 2], see also the references therein.
(ii) The needed codes are obtained by computer search, using the leximatrix algorithm.

Proposition 4.1 implies assertions of Theorem 1.4(ii).
Lengths of $\left[n_{q}^{L}(5,3), n_{q}^{L}(5,3)-5,5\right]_{q} 3$ leximatrix Almost MDS codes are collected in Table 2 (see Appendix) and presented in Figure 4 by the bottom solid black curve. The bound $3 \sqrt[3]{q^{2} \ln q}$ is shown in Figure 4 by the top dashed-dotted red curve.

We denote by $\delta_{q}(5,3)$ the difference between the bound $3 \sqrt[3]{q^{2} \ln q}$ and length $n_{q}^{\mathrm{L}}(5,3)$ of the leximatrix code. So,

$$
\delta_{q}(5,3)=3 \sqrt[3]{q^{2} \ln q}-n_{q}^{\mathrm{L}}(5,3)
$$

Figure 4: Lengths $n_{q}^{\mathrm{L}}(5,3)$ of $\left[n_{q}^{\mathrm{L}}(5,3), n_{q}^{\mathrm{L}}(5,3)-5,5\right]_{q} 3$ leximatrix codes (quasiperfect Almost MDS codes) (bottom solid black curve) vs bound $3 \sqrt[3]{q^{2} \ln q}$ (top dashed-dotted red curve), $q \leq 563$

Figure 5: Difference $\delta_{q}(5,3)$ between bound $3 \sqrt[3]{q^{2} \ln q}$ and length $n_{q}^{\mathrm{L}}(5,3)$ of $\left[n_{q}^{\mathrm{L}}(5,3), n_{q}^{\mathrm{L}}(5,3)-5,5\right]_{q} 3$ leximatrix code, $q \leq 563$

Figure 6: Percent difference $\delta_{q}^{\%}(5,3)=\frac{3 \sqrt[3]{q^{2} \ln q}-n_{q}^{\mathrm{L}}(5,3)}{3 \sqrt[3]{q^{2} \ln q}} 100 \%$ between bound $3 \sqrt[3]{q^{2} \ln q}$ and length $n_{q}^{\mathrm{L}}(5,3)$ of $\left[n_{q}^{\mathrm{L}}(5,3), n_{q}^{\mathrm{L}}(5,3)-5,5\right]_{q} 3$ leximatrix code, $q \leq 563$

The difference $\delta_{q}(5,3)=3 \sqrt[3]{q^{2} \ln q}-n_{q}^{\mathrm{L}}(5,3)$ and the percent difference $\delta_{q}^{\%}(5,3)=$ $\frac{3 \sqrt[3]{q^{2} \ln q}-n_{q}^{\mathrm{L}}(5,3)}{3 \sqrt[3]{q^{2} \ln q}} 100 \%$ are presented in Figures 5 and 6 , respectively.

By (2.1), we represent length of an $\left[n_{q}^{L}(5,3), n_{q}^{L}(5,3)-5,5\right]_{q} 3$ leximatrix code in the form

$$
\begin{equation*}
n_{q}^{\mathrm{L}}(5,3)=c_{q}^{\mathrm{L}}(5,3) \sqrt[3]{q^{2} \ln q} \tag{4.1}
\end{equation*}
$$

where $c_{q}^{\mathrm{L}}(5,3)$ is a coefficient entirely given by $q$. The coefficients $c_{q}^{\mathrm{L}}(5,3)=\frac{n_{q}^{\mathrm{L}}(5,3)}{\sqrt[3]{q^{2} \ln q}}$ are shown in Figure 7.

Figure 7: Coefficients $c_{q}^{\mathrm{L}}(5,3)=n_{q}^{\mathrm{L}}(5,3) / \sqrt[3]{q^{2} \ln q}$ for $\left[n_{q}^{\mathrm{L}}(5,3), n_{q}^{\mathrm{L}}(5,3)-5,5\right]_{q} 3$ leximatrix codes (quasiperfect Almost MDS codes), $q \leq 563$

Observation 4.2. (i) The difference $\delta_{q}(5,3)$ tends to increase when $q$ grows, see Figures 4 and 5.
(ii) The percent difference $\delta_{q}^{\%}(5,3)$ tends to increase when $q$ grows, see Figure 6 .
(iii) Coefficients $c_{q}^{L}(5,3)$ tend to decrease when $q$ grows, see Figure 7 .

Observations 4.2 (i) and 4.2 (ii) give rise to Conjecture 1.5 for $[n, n-5]_{q} 3$ codes. Note that Observations 4.2 (ii) and 4.2 (iii) directly follow each from other. Really,

$$
\delta_{q}^{\%}(5,3)=\frac{3 \sqrt[3]{q^{2} \ln q}-n_{q}^{\mathrm{L}}(5,3)}{3 \sqrt[3]{q^{2} \ln q}} 100=\left(1-\frac{c_{q}^{\mathrm{L}}(5,3)}{3}\right) 100 .
$$

## 5 Conclusion

The length function $\ell_{q}(r, R)$ is the smallest length of a $q$-ary linear code of covering radius $R$ and codimension $r$. In this work, we consider upper bounds on the length functions $\ell_{q}(4,3)$ and $\ell_{q}(5,3)$. For $r=3 t$ and $q=\left(q^{\prime}\right)^{3}$ upper bounds on $\ell_{q}(r, 3)$ close to a lower bound are known in literature.

In this work, by computer search in wide regions of $q$, we obtained short $[n, n-4,5]_{q} 3$ quasiperfect MDS codes and $[n, n-5,5]_{q} 3$ quasiperfect Almost MDS codes with covering radius $R=3$. For $r \neq 3 t$ and values of $q \neq\left(q^{\prime}\right)^{3}$, the new codes imply upper bounds of the form

$$
\ell_{q}(r, 3)<c \sqrt[3]{\ln q} \cdot q^{(r-3) / 3}, \quad c \text { is a universal constant }, \quad r=4,5
$$

As far as it is known to the authors, such bounds have not been previously described in the literature.

In computer search, we use the step-by-step leximatrix algorithm to obtain parity check matrices of codes. The algorithm is a version of the recursive g-parity check algorithm for greedy codes.

In future, it would be useful to investigate and understand properties of the leximatrix algorithm and structure of leximatrices. In particular, the following is of great interest:

- Initial part of the parity check matrices that is the same for all matrices with greater prime $q$, see Proposition 3.1 and Example 3.2 .
- The working mechanism and its quantitative estimates for the leximatrix algorithm; see, for instance, the work [1] where the working mechanism of a greedy algorithm for complete arcs in the projective plane $\operatorname{PG}(2, q)$ is studied.
- The oscillation of the coefficients $c_{q}^{\mathrm{L}}(4,3)$ around a horizontal line and its likenesses with the oscillation of the values $h^{\mathrm{L}}(q)$ around a horizontal line in [2, Fig. 12, Observation 3.7], [3, Fig. 5, Observation 3.7], see Figure 3 and Remark 3.5 .

[^0]:    *The research of D. Bartoli, S. Marcugini, and F. Pambianco was supported in part by Ministry for Education, University and Research of Italy (MIUR) (Project "Geometrie di Galois e strutture di incidenza") and by the Italian National Group for Algebraic and Geometric Structures and their Applications (GNSAGA - INDAM). The research of A.A. Davydov was carried out at the IITP RAS at the expense of the Russian Foundation for Sciences (project 14-50-00150). This work has been carried out using computing resources of the federal collective usage center Complex for Simulation and Data Processing for Mega-science Facilities at NRC Kurchatov Institute, http://ckp.nrcki.ru/.
